

// the.shared.blind.spot

The error no one catches.

When both graders agree — and both are wrong. A short story from our NASSCOM research. Swipe through.

// the.setup

01

A question needed eight entries.

The student wrote six. Two of the required entries were simply never attempted — an objective gap, not a matter of marking taste.

// they.agreed

02

Both gave full marks.

Teacher

4/4

Our AI

4/4

They agreed — so under any teacher-vs-AI check, this looks resolved. And both were wrong.

// the.catch

03

The panel gave **three**.

Value-point panel

3/4

Reading value-point by value-point against the scheme, it saw the two missing entries neither grader had docked. An entry is present or it is not.

04

When two markers agree, nobody looks again.

That is exactly where a student quietly loses. Every teacher-vs-AI comparison is blind to it — it is only visible one value-point at a time.

// the.principle

A referee reads the answer, not the other grader.

Judged against the scheme, on the evidence — with a human as the final authority. That is the layer we are building.
(Illustrative case from a small research corpus — mechanism, not a population rate.)
